Personal communication from Dr. Joel Weinstock

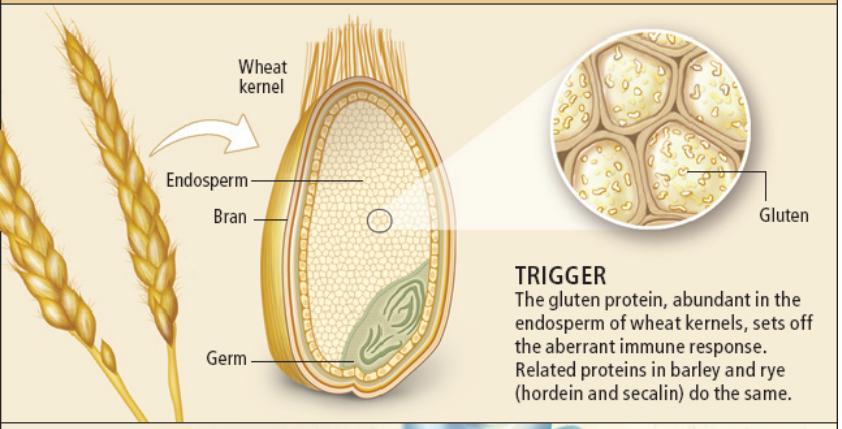
The Hygiene Hypothesis Has Been Recently Questioned

Improved Hygiene In Some Developing Countries Was Not Paralleled by Increased Autoimmune Diseases

Celiac Disease As A Unique Model of Autoimmunity

A TRIO OF CAUSES

Three factors underlie celiac disease: an environmental trigger, a genetic susceptibility and, according to the author's research, an unusually permeable gut (*below*). The author suspects that the same basic triad contributes to other autoimmune diseases, although each disorder will have its own triggers and genetic components.

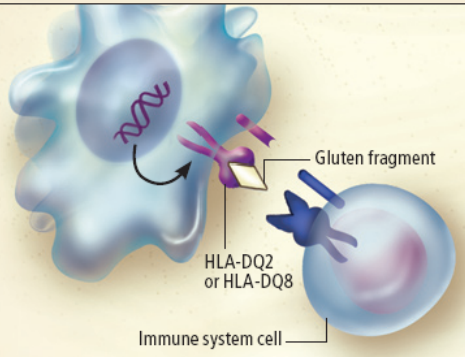


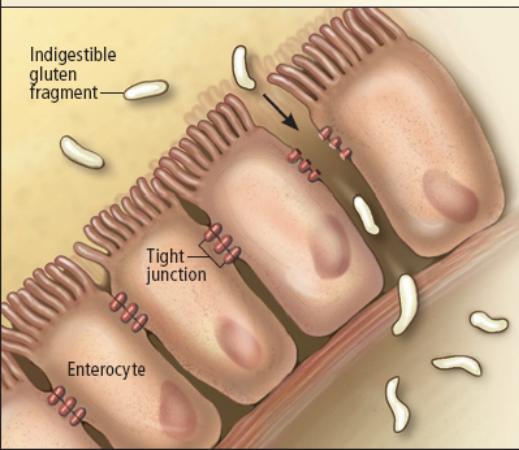
TRIGGER

The gluten protein, abundant in the endosperm of wheat kernels, sets off the aberrant immune response. Related proteins in barley and rye (hordein and secalin) do the same.

GENETIC PREDISPOSITION

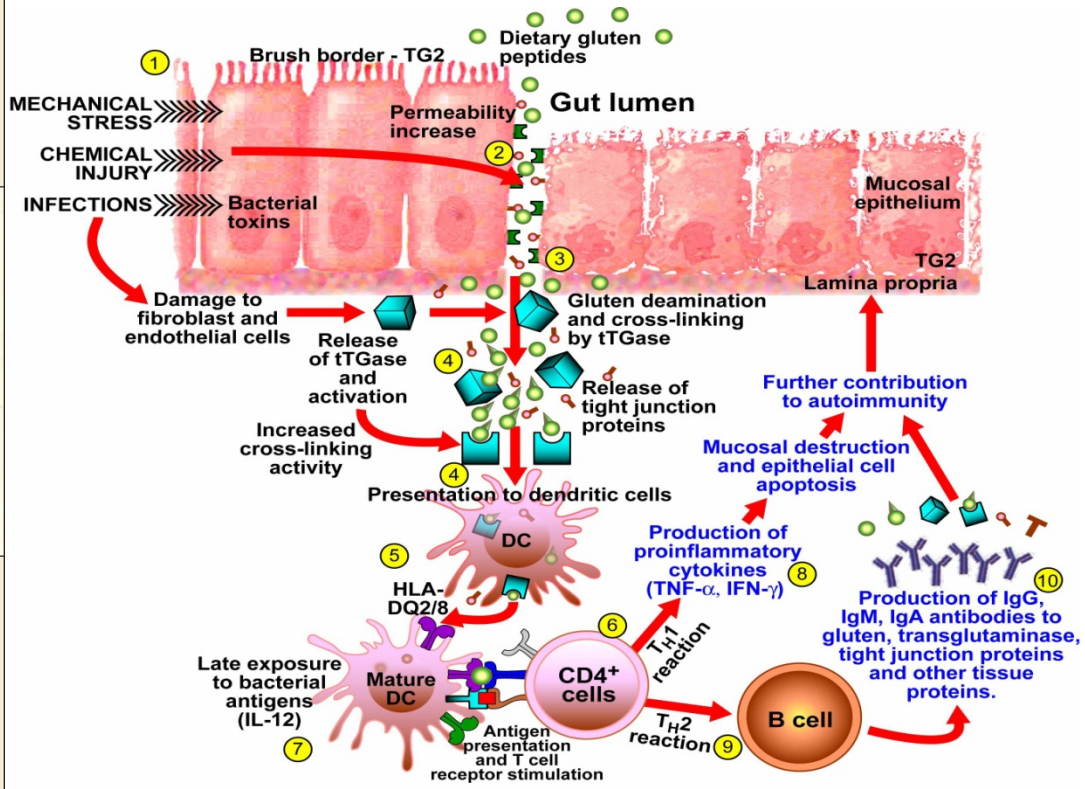
Almost all patients harbor the genes *HLA-DQ2* or *HLA-DQ8*, or both. These genes give rise to proteins of the same name that display gluten fragments to immune system cells, which then direct an attack on the intestinal lining. Other genes are likely to be involved as well, but these additional culprits may differ from person to person.





LEAKY SMALL INTESTINE

In most people, links known as tight junctions "glue" intestinal cells together. In those with celiac disease, the junctions come apart, allowing a large amount of indigestible gluten fragments to seep into the underlying tissue and incite immune system cells. Treatments that reduced leakiness could potentially ease not only celiac disease but also other autoimmune disorders involving unusually permeable intestines.



Depiction of the intestinal mucosa with emphasis on the factors involved in the development of celiac disease in individuals with HLA-DQ2/DQ8 positive

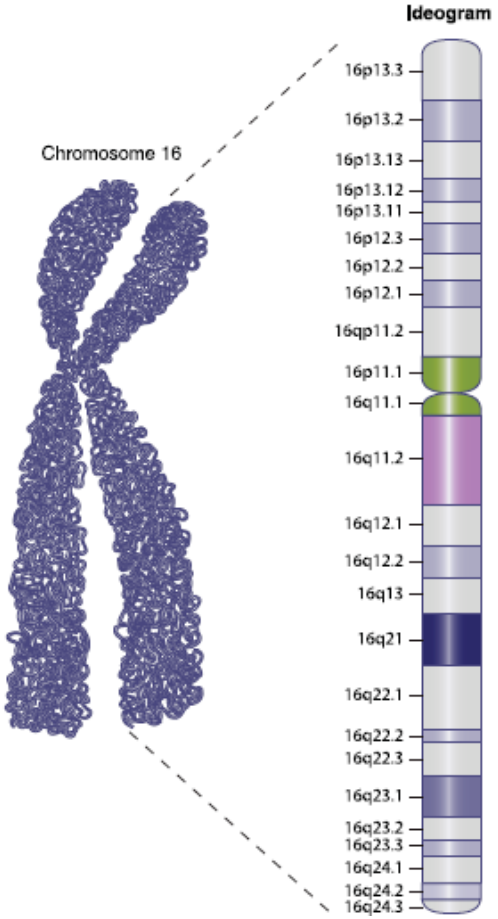
Zonulin Gene Is Located on Chromosome 16

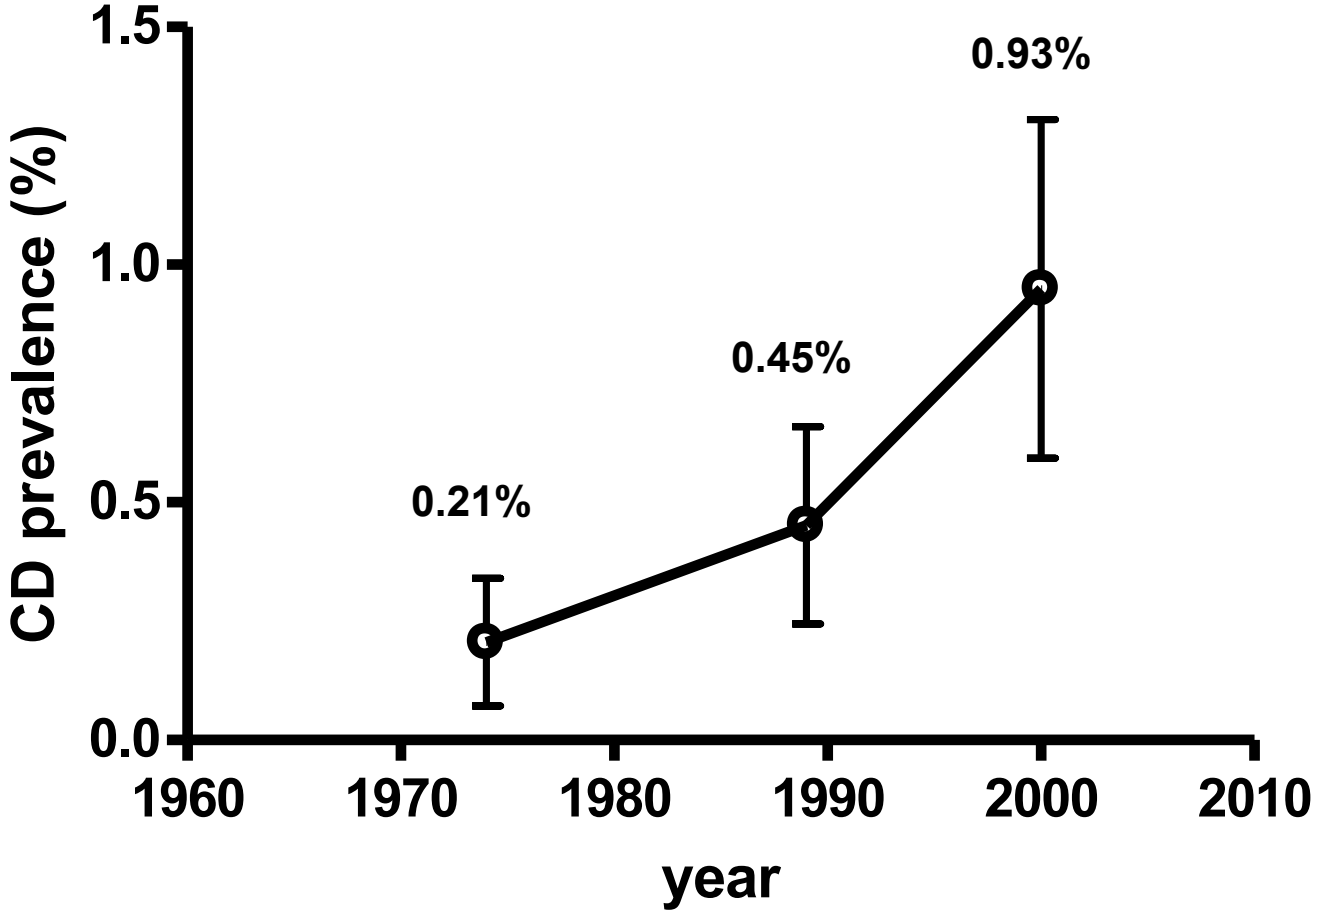
Chromosome 16 contains about 98 million bases, or some 3% of the human genome, encoding for ~1,300 genes.



Fasano A. Physiol Rev. 2011 Jan;91(1):151-75

Increased Prevalence Over Time in U.S.A.

(in Line with Other Autoimmune Diseases)



During the past 35 years the true prevalence of CD in USA doubled every 15 years.

The Epidemics Of Celiac Disease:
Which Additional Factors are Driving this Epidemics?

- Quality of gluten: GE grains
- Quantity of gluten;
- Breast Feeding;
- Timing of gluten introduction
- Maturity of gut functions influencing Ag trafficking and handling:
    - GALT
    - PRRs
    - Mucous production
    - Barrier function
- Changes in microbiome composition.

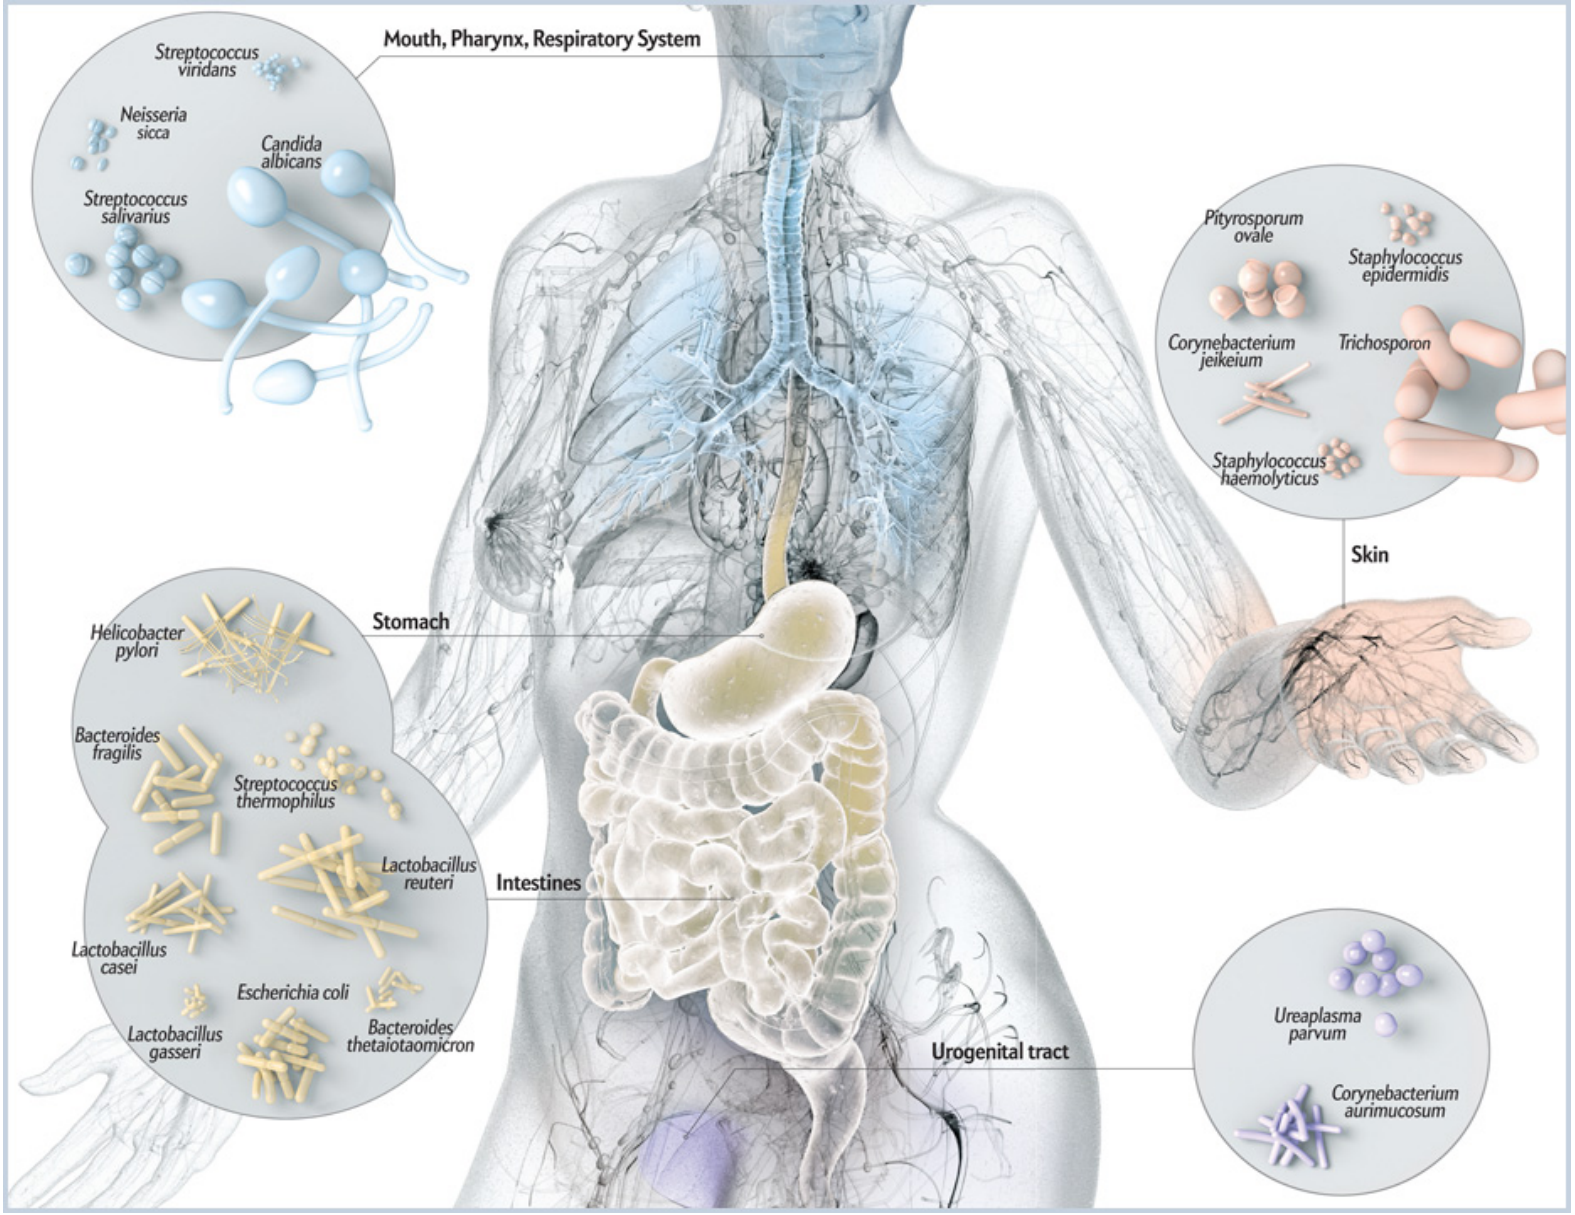
Home Take Messages

- **Window of tolerance concept (4-7 months best period to introduce baby food) not supported anymore;**
- **Breast feeding in general or introduction of gluten while breast feeding showed no protective effect on CD onset in at-risk infants;**
- **Early introduction (16 weeks) of gluten traces to potentially induce tolerance did not protect against CD in at-risk infants;**
- **Delaying the introduction of gluten in at-risk infants does not prevent CD but merely postpones its onset by approximately 8 months (significant difference at 2 years FU that disappeared by 5 years FU);**
- **GI infections during the first year of life seems influential in increased the risk of CD onset;**
- **High-risk HLA profiles seems to be the most influential factor predictor of increased risk of CD onset;**
- **The high prevalence of CD among the study cohort suggests that the CD epidemics continues.**

The Epidemics Of Celiac Disease:
Which Additional Factors are Driving this Epidemics?

- Quality of gluten;
- Quantity of gluten;
- Breast Feeding;
- Timing of gluten introduction
- Maturity of gut functions influencing Ag trafficking and handling:
    - GALT
    - PRRs
    - Mucous production
    - Barrier function
- Changes in microbiome composition.



- The human gut harbors 10^{11}-10^{12} bacteria per gram colonic content (>10^{14} total bacteria)
- Total bacteria outnumber human cells 10:1
- Total bacterial genes outnumber human genes >150:1
- >10,000 different species of bacteria are resident in the human intestinal microbiota (400-500 per person)

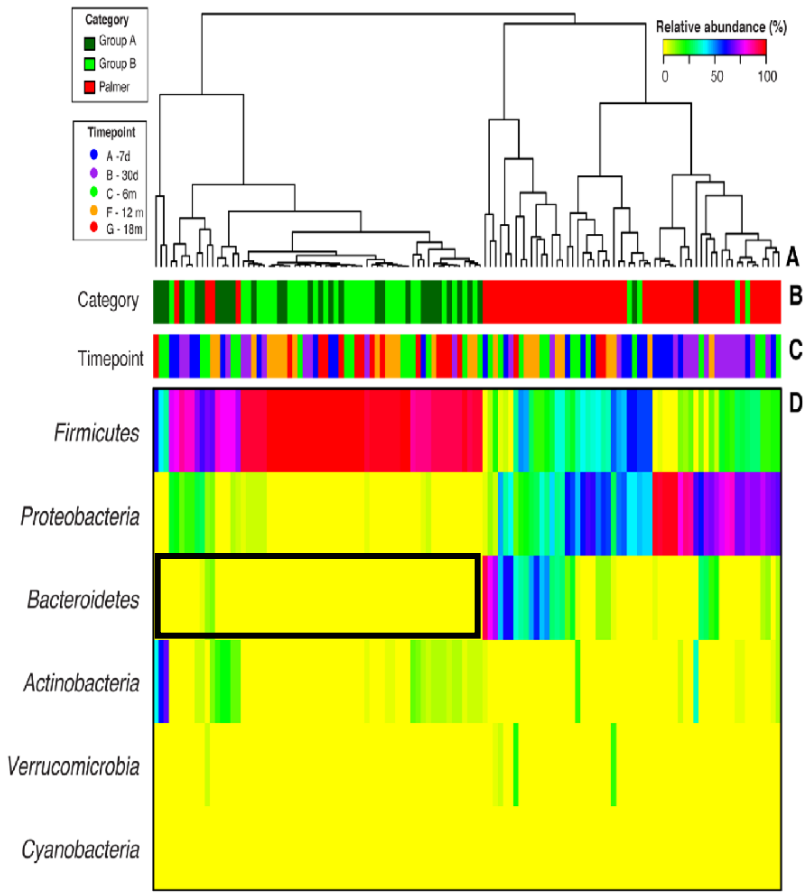
Development of the Human Infant Intestinal Microbiota

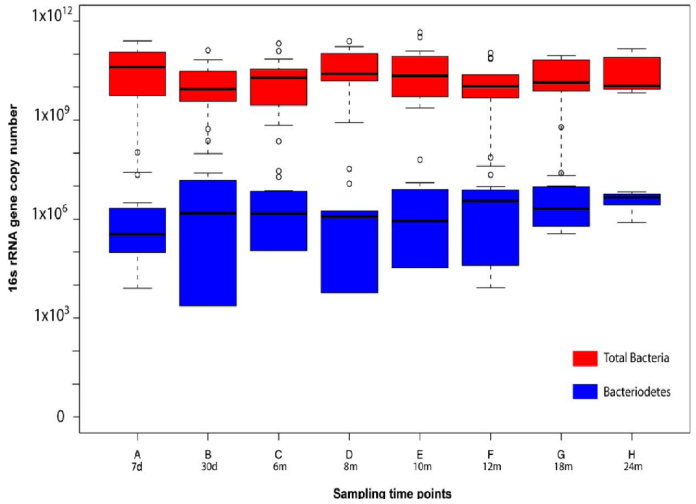
Chana Palmer[1], Elisabeth M. Bik[2], Daniel B. DiGiulio[3,4], David A. Relman[2,3,4], Patrick O. Brown[5,6*]

- The earliest colonizers were often organisms predicted to be aerobes (e.g., Staphylococcus, Streptococcus, and Enterobacteria), whereas the later colonizers tended to be strict anaerobes (Eubacteria and Clostridia).
- The Bacteroides varied greatly from baby to baby in the timing of their first appearance, but were **consistently** present in nearly all babies by 1 y.
- Several other taxa, including Prevotella, Acinetobacter, Desulfovibrio, Veillonella, and Clostridium perfringens, tended to appear only transiently, sometimes appearing and disappearing repeatedly within a baby's first year of life.
- By the end of the first year of life, the microbial ecosystems in each baby had converged toward a profile characteristic of the adult GI tract.
- **All these changes are mainly driven by nutritional variables**

Proof of Concept of Microbiome-Metabolome Analysis and Delayed Gluten Exposure on Celiac Disease Autoimmunity in Genetically At-Risk Infants

Maria Sellitto[1¤], Guoyun Bai[2], Gloria Serena[1], W. Florian Fricke[2], Craig Sturgeon[1], Pawel Gajer[2], James R. White[2], Sara S. K. Koenig[2], Joyce Sakamoto[2], Dustin Boothe[1], Rachel Gicquelais[1], Deborah Kryszak[1], Elaine Puppa[1], Carlo Catassi[1,3], Jacques Ravel[2]*, Alessio Fasano[1]*





Infants genetically predisposed to CD were characterized by a low abundance of Bacteroidetes (undetectable to 1%) combined with abundance of Firmicutes.

The Real Story of Our Genetic Complexity:

We Inherit two Parallel Genomes

Human Genome:

Inherited from both parents, stable, never change in its composition

Microbiome:

Inherited from the mother, extremely dynamic, changes from individual to individual and in the same individual over time

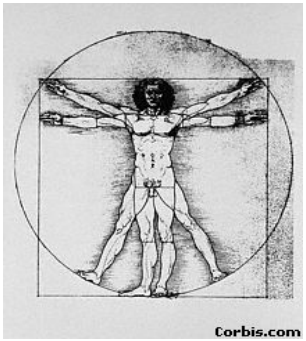
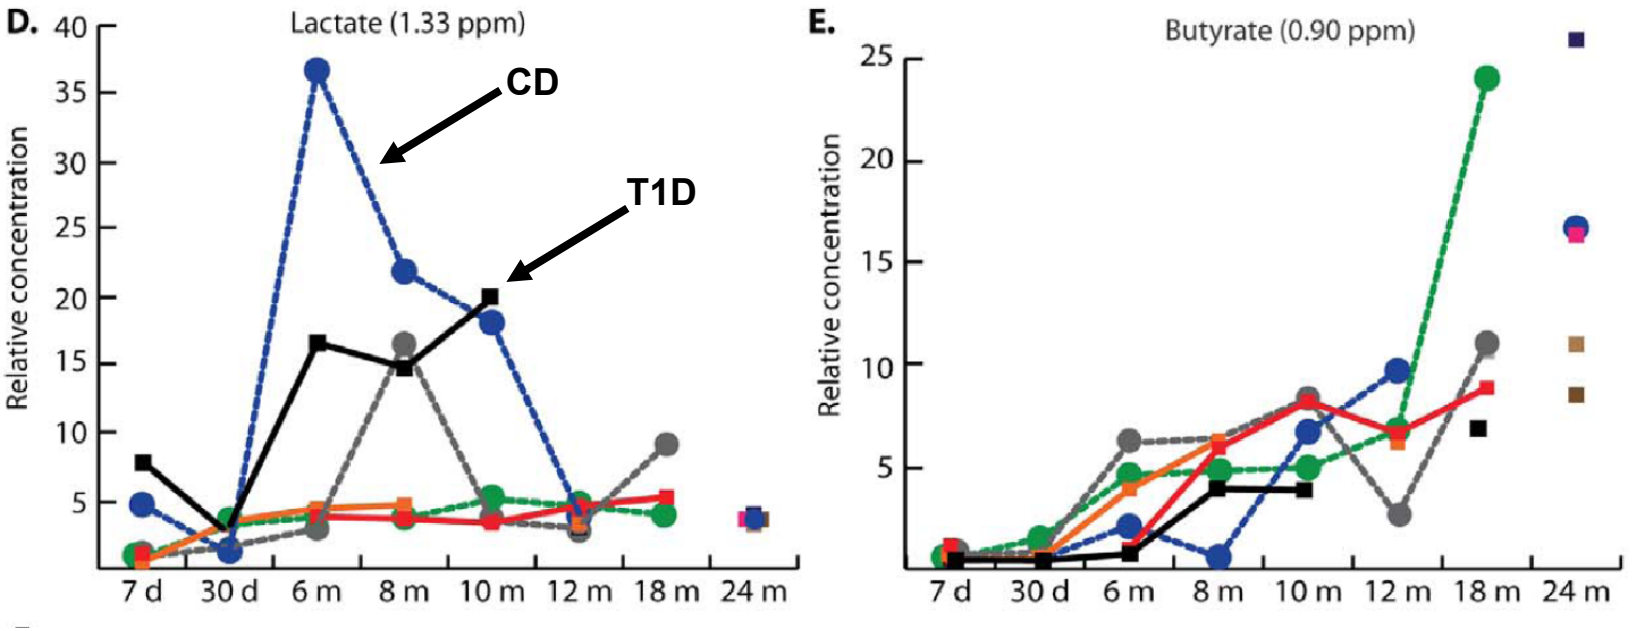
Clinical Outcome



NMR Analysis



- **Infants who developed autoimmune diseases during the time of the study had high levels of lactate combined with low levels of butyrate before the onset of the disease.**

- **During the active state of the disease (24 months) the same subjects showed an increase in butyrate production and a decrease in lactate, therefore suggesting that the acute phase of CD is characterized by a different metabolomic profile.**

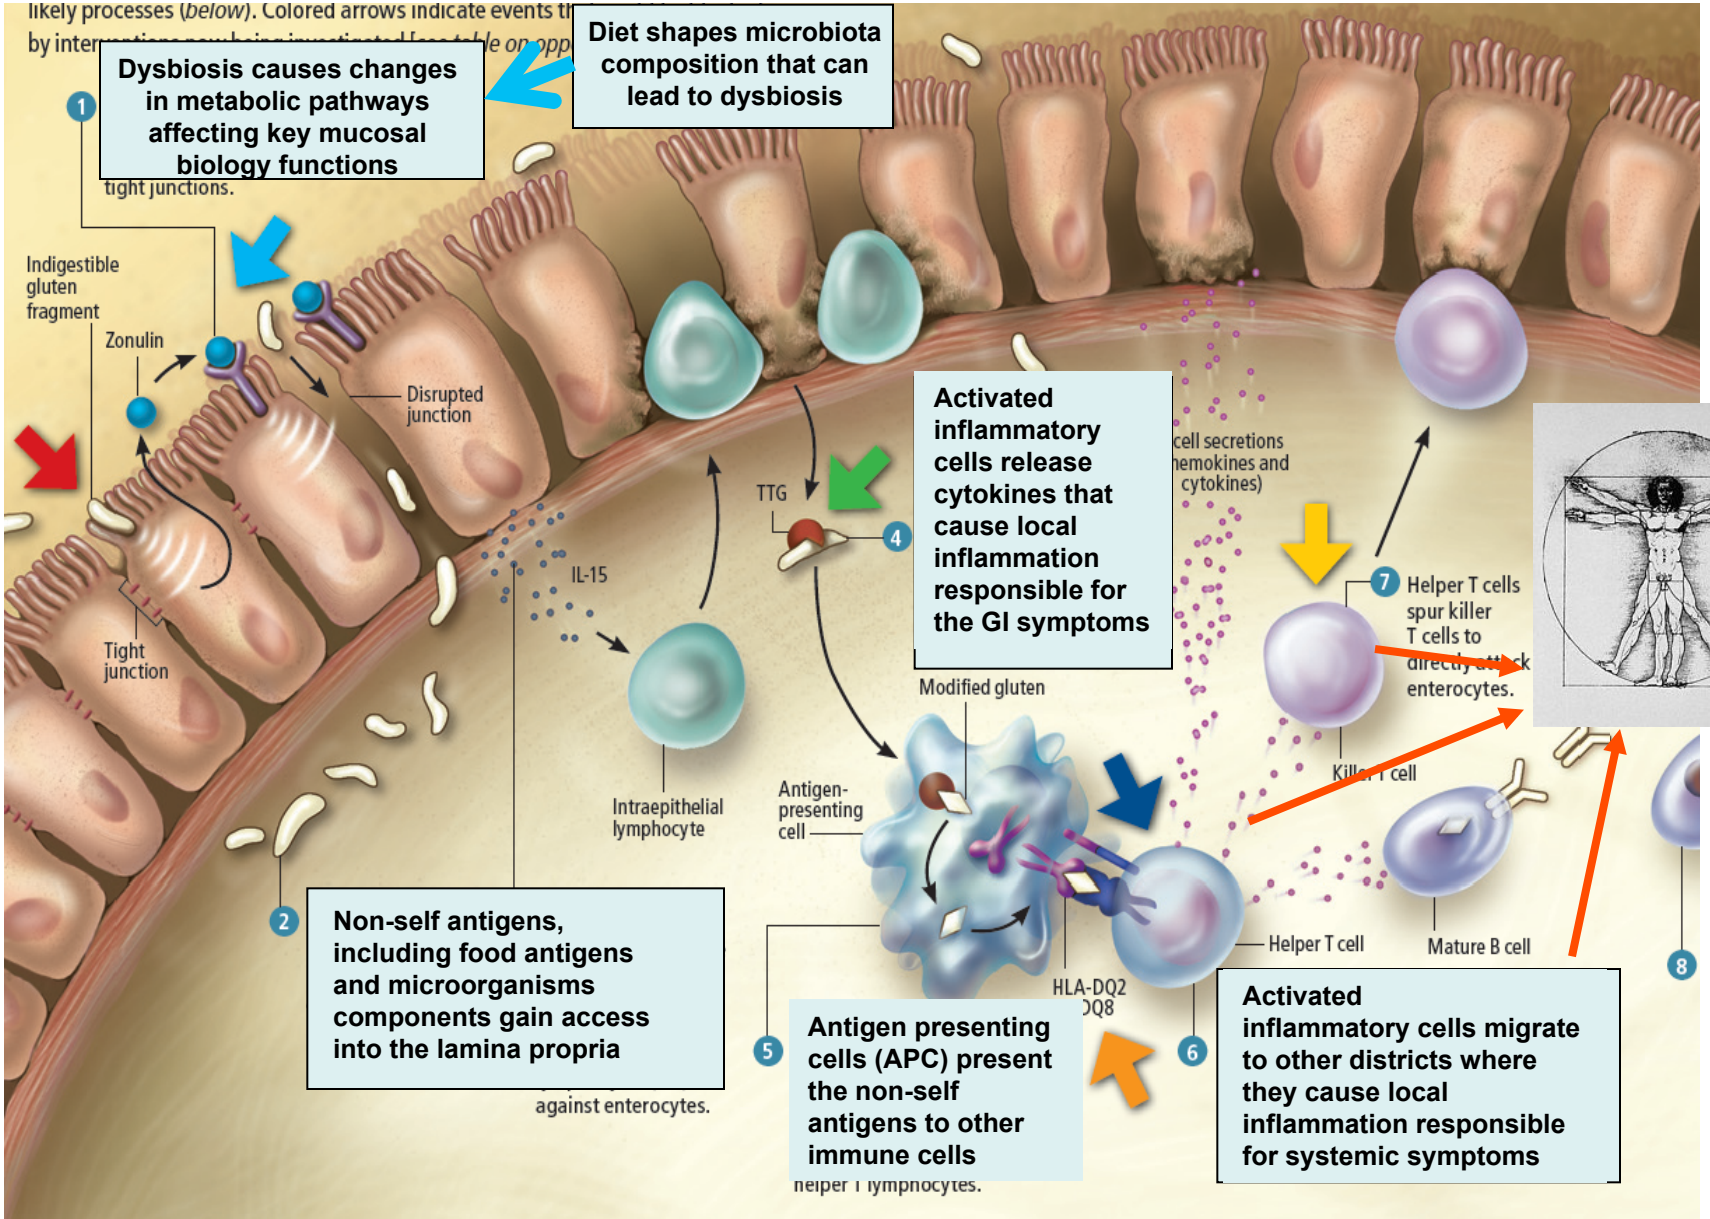
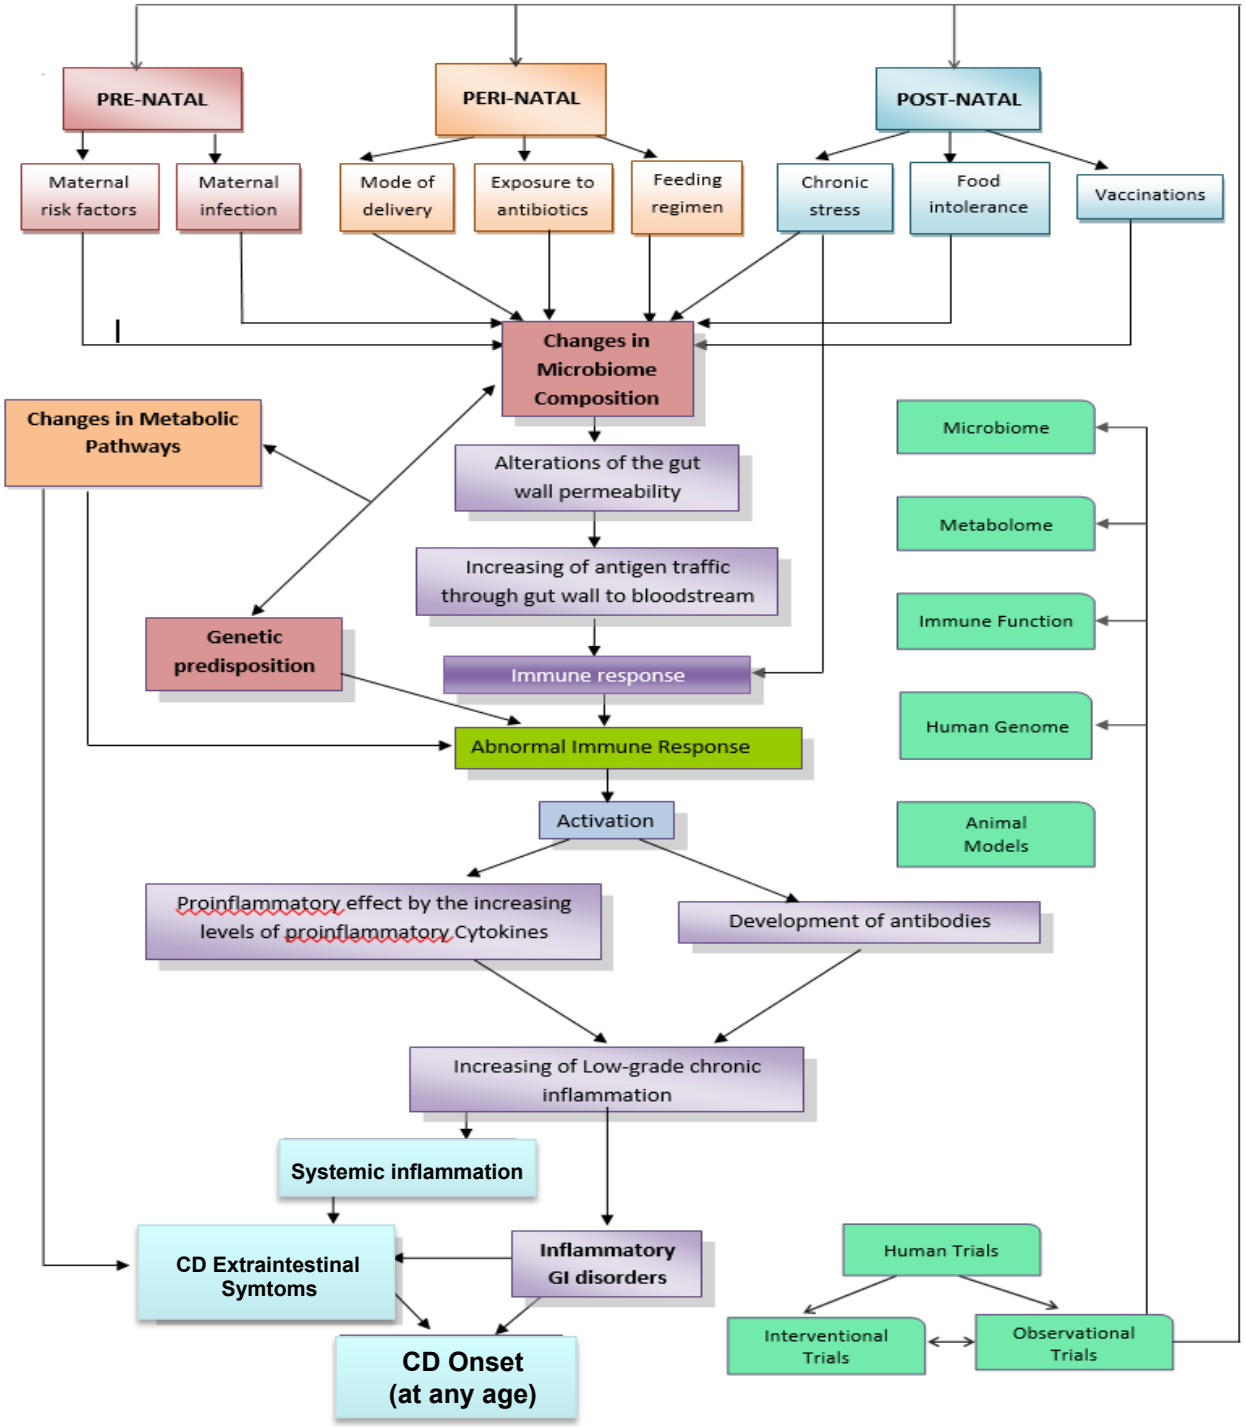
Hypothesis

Combination of introduction of gluten into the diet and particular microbiota composition of infants genetically at risk for CD activates specific metabolic pathways that can contribute to the loss of tolerance to gluten and to the onset of autoimmunity, as reflected by specific metabolomic phenotypes

Working Hypothesis of the CD-GEMM Project





PRE-NATAL
PERI-NATAL
POST-NATAL
Maternal risk factors
Maternal infection
Mode of delivery
Exposure to antibiotics
Feeding regimen
Chronic stress
Food intolerance
Vaccinations
Changes in Microbiome Composition
Changes in Metabolic Pathways
Alterations of the gut wall permeability
Increasing of antigen traffic through gut wall to bloodstream
Genetic predisposition
Immune response
Abnormal Immune Response
Activation
Proinflammatory effect by the increasing levels of proinflammatory Cytokines
Development of antibodies
Increasing of Low-grade chronic inflammation
